## Keywords: Homoallylic Alcohols, Cyclization, Hypervalent Iodine

Abstract

Cyclofunctionalization of homoallylic alcohols with iodine/iodine (III) system to obtain tetrahydrofuran derivatives.

### Introduction

There is an interest on synthesis of substituted tetrahydrofuran (THF) moiety because they are present in many biological activity compounds.<sup>1</sup> Our group described a methodology to THF synthesis from tertiary homoallylic alcohols with terminal double bond using iodine/iodine(III). The mechanism using HTIB (PhI(OH)OTs) is described in **Scheme 1**.

**Scheme 1 – I**<sub>2</sub>/I(III) cyclization mechanism

Some experimental evidences suggests two differents ways mechanism.<sup>2</sup> Pathway **A** is derived from the internal hydroxyl group attack to producing oxetane **2a**. The iodine(III) specie **3a** are generated from iodine oxidation followed from a ligand elimination. The hypernucleofuge characteristic of hypervalent specie drives the bicyclic oxonium ion **4** formation.<sup>2</sup> Finally, MeOH attacks affording THF **5**. Pathway **B** arrives from solvent attack generating **2b** followed by iodine oxidation (**3a**). Cyclization by an intramolecular hydroxyl attack led the cyclic ether formation. We have already shown some examples for secondary alcohols.<sup>3</sup> Herein the scope was expanded and is also presented some results from other substrates

## **Results and discussion**

The cyclization of secondary homoallylic alcohols with HTIB and  $I_2$  led to the formation of the desired products (**Table 1**). Applying this methodology to primary homoallylic alcohol, we observed the desired THF product, however, the rearrangement product was the mainly isolated (**Scheme 2A**).

<sup>a</sup> result previusly presented in 15<sup>th</sup> BMOS <sup>b</sup> cis/trans product determined by NOESY 1D experiment

Using 4-alkenol as substrate, the iodoether product observed (**Scheme 2B**). Performing the reaction with the unsaturated carboxylic acid only the rearrangement product was isolated (**Scheme 2C**). Reacting the carboxylic acid with iodine under basic conditions,  $\beta$ -iodolactone **8** was obtained in quantitative yield. Aiming the ring expansion product, was performed a reaction with HTIB, but only rearrangement product **7** was formed.

Scheme 2 – I<sub>2</sub>/I(III) mediated cyclization reactions

#### Conclusion

lodine/iodine(III) methodology is useful to obtaining substituted THFs employing secondary homoallylic alcohols. Employing primary alcohols and unsaturated acid, the rearrangement product was observed.
